1 Introduction

Diseases like Alzheimer and Parkinson disease are the result of proteins aggregating into large fractal structures that hinder the cell function or even destroy them. Understanding how aggregates are formed and change over time is important to understand when they become harmful and how maybe treatments affect aggregate formation.

The goal of this Internship is to implement a simulation system to study aggregation between proteins. This work is performed in collaboration with the Switch lab in the KU Leuven, who has an extensive expertise in studying aggregation and related diseases.

2 First 2 weeks (12th-23rd August)

During the first week of the Internship, I spent the first few days getting used to the work environment, did my computer and office set up, got to know my team mates and the routines (lunch time, group lunches etc) and some paperwork so that I was given access to IB2 on a daily basis. Once I settled down, I researched the subject and mostly did a state of the art to have a baseline knowledge.

3 Third week (26th-31st August)

Having acquired a basic understanding, during the third week, I refined my reasearch and focused on the specific papers discussing the problem in order to have a deeper understanding of the theory before starting any kind of implementation. The papers I focussed on are the following [Gil76], [MKA⁺16], [GB00], [JSMI12].

4 Fourth week (2nd-6th September)

The goal of this week was to implement a simple prototype (in python for now) of an exact numerical simulation method to simulate trajectories of discrete, stochastic systems.

4.1 Gillespie's stochastic framework of chemical kinetics

The principle task is to develop a method for simulating the time evolution of the N quantities $\{X_i\}$, knowing only their initial values $\{X_i^{(0)}\}$, the form of the M reactions $\{R_{\mu}\}$ and the values of the reaction parameters $\{c_{\mu}\}$.

Definition 1. Problem definition: We are given a volume V containing molecules of N chemically active species $S_i (i = 1, ..., N)$. Let $X_i \equiv \text{current number of molecules of chemical species } S_i \in V, (i = 1, 2, ..., N)$ and let $R_{\mu}(\mu = 1, ..., M)$ be the chemical reactions in which the species S_i can participate. Each reaction R_{μ} is characterized by a numerical

reaction parameter c_{μ} and let R be the different type of reactions:

$$* \rightarrow reaction products$$
 (1)

$$S_i \to reaction products$$
 (2)

$$S_j + S_k \to reaction products$$
 (3)

$$2S_j \to reaction products$$
 (4)

$$S_i + S_j + S_k \to reaction products$$
 (5)

$$S_j + 2S_k \to reaction products$$
 (6)

$$3S_j \to reaction products$$
 (7)

, the goal is to simulate the trajectories of the N chemically active species S_i and predict which reaction will occur at each time step according to the correct probability distribution.

Hypothesis 2. The reaction parameter c_{μ} can be defined as follows: $c_{\mu}\delta t \equiv average$ probability that a particular combination of R_{μ} reactant molecules will react accordingly in the next time interval δt (first order).

Definition 3. State of the system is defined by the number of molecules of each species and changes discretely whenever one of the reactions is executed. The probability that a certain reaction μ will take place in the next instant of time is given by $a_{\mu}dt + o(dt)$.

4.2 Gillespie's Direct Method

Given the problem defined above, the Gillespie's Direct Method answers two questions:

- 1. Which reaction occurs next?
- 2. When does it occur?

4.2.1 Gillespie's Direct Method formulas

- 1. Probability density $P(\mu, \tau)$ that the next reaction is μ and it occurs at time $\tau \to P(\mu, \tau)d\tau = a_{\mu}exp(-\tau \sum_{j} a_{j})d\tau$.
- 2. Probability for reactions $\rightarrow Pr(Reaction = \mu) = a_{\mu} / \sum_{j} a_{j}$.
- 3. Probability distribution for times $\rightarrow P(\tau)d\tau = (\sum_j a_j)exp(-\tau \sum_j a_j)d\tau$.

4.3 Gillespie's Direct Method: Pseudo code

1

4.4 Gillespie's Direct Method : Example

Example 4. Generating a sample trajectory of a chemical process in the stochastic framework: Direct Method

Algorithm 1 Gillespie's Direct Method

Input: N chemically active species S_i , $\{X_i^{(0)}\}$ initial values of each species S_i , the set R of chemical reactions and the reaction parameter c_{μ} for each reaction.

Output: Sample trajectory of a chemical process in the stochastic framework.

while !(simulation time exceeded) do

- 1. Initialization: Set initial number of molecules in the system, set $t \leftarrow 0$.
- 2. Calculate the propensity function, $a_i, \forall i$.
- 3. Choose μ according to the distribution in 2.
- 4. Choose τ according to an exponential with parameter $\sum_{j} a_{j}$ as in 3.
- 5. Update the number of molecules to reflect execution of reaction μ . Set $t \leftarrow t + \tau$.
- 6. Go to step 2.

end while

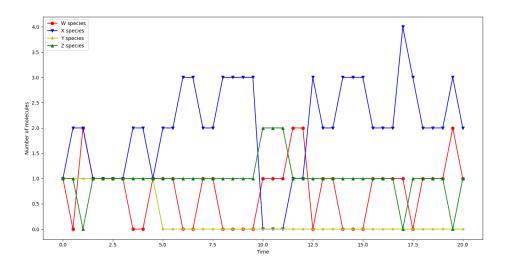

Figure 1: The x-axis denotes the duration time of the simulation and the y-axis denotes the number of molecules of each species S_i at each time step.

4.5 Gillespie's Direct Method: Implementation

The source code of the simple simulation model can be found at Direct-method-github. The reaction set is the example used in Gillespie's paper [Gil76].

$$X \xrightarrow{c_1} Y \tag{8}$$

$$Y \xrightarrow{c_2} X$$
 (9)

$$2X \xrightarrow{c_3} Z$$
 (10)

$$Z \xrightarrow{c_4} 2X$$
 (11)

$$W + X \xrightarrow{c_5} 2X \tag{12}$$

$$2X \xrightarrow{c_6} W + X \tag{13}$$

The reaction parameter c_{μ} is chosen randomly and the initial number of each species is = 1.

5 Fifth week (9th-20th September)

5.1 Gillespie's Next Reaction Method

The goal of those two weeks was to implement the Gillespie Next Reaction Method in order to be able to consider larger systems. The main idea behind the Next Reaction Method is to generate a putative time τ_i for each reaction i to occur and choose the reaction μ whose putative time τ_{μ} is least. In order to minimize the computation time, the Next Reaction Method is implemented using specific data structures.

Definition 5. Let Reactants(ρ) and Products(ρ) be the set of reactants and products respectively of a reaction μ .

Definition 6. Let a_{μ} be the value computed by the propensity function and Depends $On(a_{\mu})$ be the set of substances that affects the value a_{μ} .

Definition 7. Let $Affects(\mu)$ be the set of substances that are affected if reaction μ occurs.

Definition 8. [GB00] Given a set of reactions R, the graph G = G(V, E) is a directed graph where V is the set of reactions and there exists an edge from v_i to v_j if and only if $Affects(v_i) \cap DependsOn(a_{v_j}) \neq \emptyset$. G is then referred to as the dependency graph of the set of reactions R and precise exactly which a_i s to change when a given reaction occurs.

Definition 9. Indexed priority Queues: An indexed priority queue is a generic priority queue with random access to its elements through an index structure.

5.2 Gillespie's Next Reaction Method: Pseudo code

2

5.3 Gillespie's Next Reaction Method: Examples

Example 10. Generating a sample trajectory of a chemical process in the stochastic framework: Next Reaction Method.

5.4 Gillespie's Next Reaction Method: Implementation

The source code Next Reaction Method can be found at Next-Reaction-Method-github. The reaction set is the example used in the following paper [GB00].

$$A + B \xrightarrow{k_1} C \tag{14}$$

$$B + C \xrightarrow{k_2} D \tag{15}$$

$$D + E \xrightarrow{k_3} E + F \tag{16}$$

$$F \xrightarrow{k_4} D + G$$
 (17)

$$E + G \xrightarrow{k_5} A \tag{18}$$

(19)

Algorithm 2 Gillespie's Next Reaction Method

Input: N chemically active species S_i , $\{X_i^{(0)}\}$ initial values of each species S_i , the set R of chemical reactions and the reaction parameter c_{μ} for each reaction.

Output: Sample trajectory of a chemical process in the stochastic framework.

while !(simulation time exceeded) do

- 1. Initialization:
 - 1.1 set initial number of molecules, set $t \leftarrow 0$, generate a dependency graph G.
 - 1.2. calculate the propensity function, $a_i, \forall i$.
 - 1.3. for each i, generate a putative time, τ_i , according to an exponential distribution with parameter a_i .
 - 1.4. store the τ_i values in an indexed priority queue P.
- 2. Let μ be the reaction whose putative time, τ_{μ} , is least.
- 3. Let τ be τ_{μ} .
- 4. Update the number of molecules to reflect execution of reaction μ . Set $t \leftarrow \tau$.
- 5. For each edge(μ , α) in the dependency graph G,
 - 5.1 update a_{α} .
 - 5.2 if $\alpha \neq \mu$, set $\tau_{alpha} \leftarrow (a_{\alpha,old}/a_{\alpha,new})(\tau_{\alpha} t) + t$.
 - 5.3 if $\alpha = \mu$, generate a random number, ρ , according to an exponential distribution with parameter a_{μ} and set $\tau_{\alpha} \leftarrow \tau + t$.
 - 5.4 Update the old τ_{α} value in P.
- 6. Go to step 2.

end while

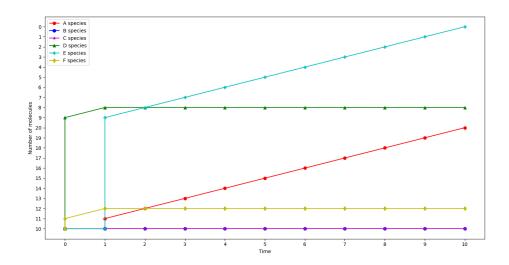

Figure 2: The x-axis denotes the time used and the y-axis denotes the number of molecules : Sample 1

The reaction parameter k_{μ} is chosen randomly and the initial number of each species is = 10.

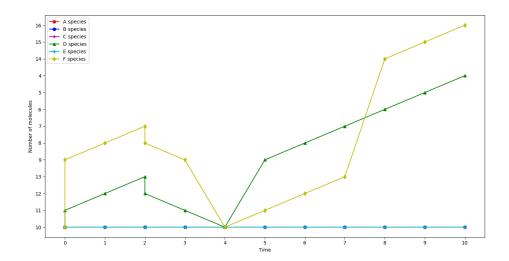

Figure 3: The x-axis denotes the time used and the y-axis denotes the number of molecules : Sample 2

5.5 Meet up with the collaborators of KU Leuven : Re-calibrate the goal

- 1. Understanding the lag phase in the amyloid fibril formation. 4
- 2. Self assembly phenomenon. 5
- 3. Finding the rate constants.

6 Following weeks

- 1. On the lag phase: Hypothesis.
- 2. On the lag phase: Solutions.
- $3. \ \, \text{On the lag phase}:$ Implementation of the solutions.

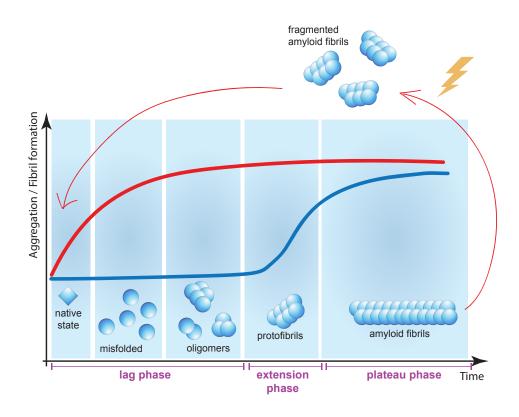

Figure 4: lag phase in the amyloid fibril formation

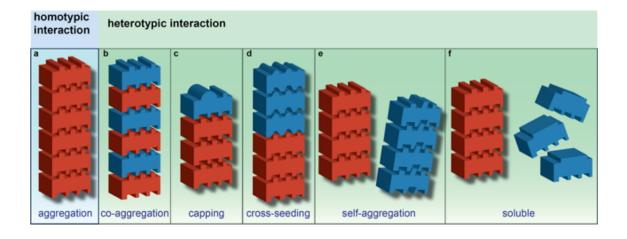

Figure 5: Amyloid stacking
